ABSTRACT

Introduction: Bladder sarcomatoid carcinoma is a very rare variant of transitional cell carcinoma. With disputed nomenclature, the tumor has been described previously under a variety of names such as sarcomatoid carcinoma, pseudosarcoma, malignant mixed mesodermal/Müllerian tumor, metaplastic carcinoma and spindle cell carcinoma. This malignancy represents 0.3% of all bladder tumors and has an aggressive behavior yielding a poor prognosis despite radio and chemotherapy. Case Report: An 81 y/o man presented with a transitional cell carcinoma and underwent a transurethral resection. Adjuvant onco-BCG was introduced. After 9 months of follow-up, a local tumoral recurrence occurred and a new transurethral resection revealed sarcomatoid carcinoma with osseous elements. A radical cystoprostatectomy was then carried out.

Key words: bladder neoplasms; transitional cell; BCG vaccine; carcinosarcoma; cystectomy

INTRODUCTION

Sarcomatoid carcinoma (SC) of the urinary bladder is a variant of Transitional Cell Carcinoma (TCC). SC contains sarcoma-like areas with either spindle or pleomorphic cells. The aggressive behavior of the tumor precludes radical therapy whenever possible, since adjuvant therapy seems to have little effect on the tumor natural history. We report on a case of SC with osseous element, with emphasis on the peculiar clinical and histopathological features.

CASE REPORT

A 81-year-old man presented with irritative lower urinary tract symptoms. Ultrasound showed thickening of the right posterior bladder wall and a cystoscopy revealed a 3 cm hyperemic verrucous lesion. Transurethral resection of the lesion was performed and the histopathology revealed a TCC with no muscle invasion. The patient presented hematuria 9 months later and a cystoscopy revealed a 5 cm tumor in the right bladder wall. Onco BCG (Bacilli Calmette-Guérin), 40 mg once a week for 8 weeks was successfully administered. Seven months later, the patient presented hematuria again. A cystoscopy with biopsy revealed a high grade, muscular invasive TCC with a pattern of sarcomatoid carcinoma with osseous differentiation. Radiotherapy had no effect. Radical cystoprostatectomy was performed with an uneventful follow-up. The surgical specimen revealed a tumoral mass of 9 cm in diameter with a histopathologic pattern of a high grade TCC (Figure-1) with osteosarcomatous heterologous elements (Figure-2). Adjacent fat tissue was tumor free. A month later, a
Sarcomatoid Carcinoma with Osseous Differentiation

The tumor has poor prognosis. Records of Mayo Clinic (1936-1995) preclude that the tumors occur predominantly in male smokers, mean age of 72 years (1). Signs and symptoms include clot hematuria, dysuria, pollakiuria and urinary infection. At initial diagnosis, almost all patients have advanced stage disease with muscularis mucosa involvement. Most patients died of local disease or of lymph node, lung, pleura, brain, liver and bone metastases.

Radical cystoprostatectomy should always be considered to bladder SC. Froehner et al. (3) reported a case of a metastatic SC remission of the bladder with cisplatin and gemcitabine, although, in the literature, adjuvant radiotherapy or adjuvant chemotherapy are apparently of no effect.

CONFLICT OF INTEREST

None declared.
